

Hashing

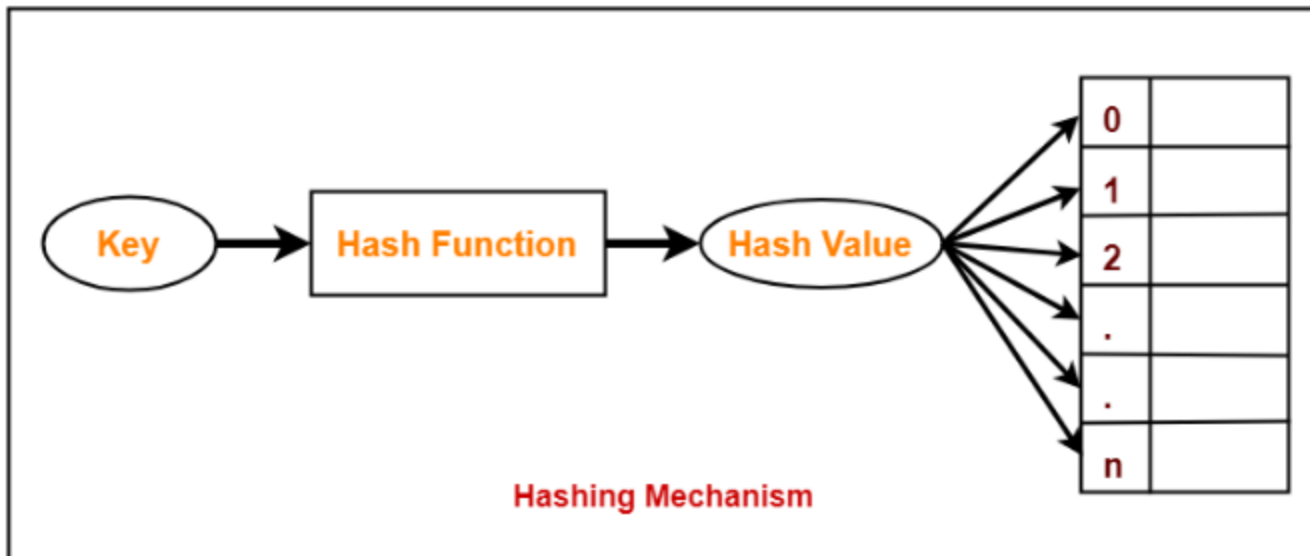

- Hashing is a well-known technique to search any particular element among several elements.
- It minimizes the number of comparisons while performing the search.
- Unlike other searching techniques,
 - Hashing is extremely efficient.
 - The time taken by it to perform the search does not depend upon the total number of elements.
 - It completes the search with constant time complexity $O(1)$.

Hashing Mechanism

- An array data structure called as **Hash table** is used to store the data items.
- Based on the hash key value, data items are inserted into the hash table.

Hash Key value

- Hash key value is a special value that serves as an index for a data item.
- It indicates where the data item should be stored in the hash table.
- Hash key value is generated using a hash function.

Hash Function

- Hash function is a function that maps any big number or string to a small integer value.
- Hash function takes the data item as an input and returns a small integer value as an output.
- The small integer value is called as a hash value.
- Hash value of the data item is then used as an index for storing it into the hash table.

Types of Hash Functions

- There are various types of hash functions available such as-
- Mid Square Hash Function
- Division Hash Function
- Folding Hash Function etc
- It depends on the user which hash function wants to use.

Properties of Hash Function

- The properties of a good hash function are-
 - It is efficiently computable.
 - It minimizes the number of collisions.
 - It distributes the keys uniformly over the table.

Collision in Hashing

- Hash function is used to compute the hash value for a key.
- Hash value is then used as an index to store the key in the hash table.
- Hash function may return the same hash value for two or more keys.
- When the hash value of a key maps to an already occupied bucket of the hash table, it is called as a **Collision**.

Collision Resolution Techniques

- Collision Resolution Techniques are the techniques used for resolving or handling the collision.

Separate Chaining

- To handle the collision,
 - This technique creates a linked list to the slot for which collision occurs.
 - The new key is then inserted in the linked list.
 - These linked lists to the slots appear like chains.
 - That is why, this technique is called as **separate chaining**.

Example-Separate Chaining

- Using the hash function 'key mod 7', insert the following sequence of keys in the hash table-
- 50, 700, 76, 85, 92, 73 and 101

Step-1

- Draw an empty hash table.
- For the given hash function, the possible range of hash values is $[0, 6]$.
- So, draw an empty hash table consisting of 7 buckets as-

0	
1	
2	
3	
4	
5	
6	

Step-2

- Insert the given keys in the hash table one by one.
- The first key to be inserted in the hash table = 50.
- Bucket of the hash table to which key 50 maps = $50 \bmod 7 = 1$.
- So, key 50 will be inserted in bucket-1 of the hash table as-

0	
1	50
2	
3	
4	
5	
6	

Step-3

- The next key to be inserted in the hash table = 700.
- Bucket of the hash table to which key 700 maps = $700 \bmod 7 = 0$.
- So, key 700 will be inserted in bucket-0 of the hash table as-

0	700
1	50
2	
3	
4	
5	
6	

Step-4

- The next key to be inserted in the hash table = 76.
- Bucket of the hash table to which key 76 maps = $76 \bmod 7 = 6$.
- So, key 76 will be inserted in bucket-6 of the hash table as-

0	700
1	50
2	
3	
4	
5	
6	76

Step-5

- The next key to be inserted in the hash table = 85.
- Bucket of the hash table to which key 85 maps = $85 \bmod 7 = 1$.
- Since bucket-1 is already occupied, so collision occurs.
- Separate chaining handles the collision by creating a linked list to bucket-1.
- So, key 85 will be inserted in bucket-1 of the hash table as-

Step-6

- The next key to be inserted in the hash table = 92.
- Bucket of the hash table to which key 92 maps = $92 \bmod 7 = 1$.
- Since bucket-1 is already occupied, so collision occurs.
- Separate chaining handles the collision by creating a linked list to bucket-1.
- So, key 92 will be inserted in bucket-1 of the hash table as-

Step-7

- The next key to be inserted in the hash table = 101.
- Bucket of the hash table to which key 101 maps = $101 \bmod 7 = 3$.
- Since bucket-3 is already occupied, so collision occurs.
- Separate chaining handles the collision by creating a linked list to bucket-3.
- So, key 101 will be inserted in bucket-3 of the hash table as-

Open Addressing

- In open addressing,
 - Unlike separate chaining, all the keys are stored inside the hash table.
 - No key is stored outside the hash table.
- Techniques used for open addressing are-
 - Linear Probing
 - Quadratic Probing
 - Double Hashing

Operations in Open Addressing

- Insert Operation:
 - Hash function is used to compute the hash value for a key to be inserted.
 - Hash value is then used as an index to store the key in the hash table.
- In case of collision,
 - Probing is performed until an empty bucket is found.
 - Once an empty bucket is found, the key is inserted.
 - Probing is performed in accordance with the technique used for open addressing.

Open Addressing

- Search Operation:
- To search any particular key,
 - Its hash value is obtained using the hash function used.
 - Using the hash value, that bucket of the hash table is checked.
 - If the required key is found, the key is searched.
 - Otherwise, the subsequent buckets are checked until the required key or an empty bucket is found.
 - The empty bucket indicates that the key is not present in the hash table.

Open Addressing

- Delete Operation:
 - The key is first searched and then deleted.
 - After deleting the key, that particular bucket is marked as “deleted”.

1. Linear Probing

- In linear probing,
 - When collision occurs, we linearly probe for the next bucket.
 - We keep probing until an empty bucket is found.
- **Advantage-**
 - It is easy to compute.
- **Disadvantage-**
 - The main problem with linear probing is clustering.
 - Many consecutive elements form groups.
 - Then, it takes time to search an element or to find an empty bucket.

Linear Probing

$$f(i) = i$$

- Probe sequence is

- $h(k) \bmod \text{size}$
- $h(k) + 1 \bmod \text{size}$
- $h(k) + 2 \bmod \text{size}$
- ...

- findEntry using linear probing:

```
bool findEntry(const Key & k, Entry *& entry) {  
    int probePoint = hash1(k);  
    do {  
        entry = &table[probePoint];  
        probePoint = (probePoint + 1) % size;  
    } while (!entry->isEmpty() && entry->key != k);  
    return !entry->isEmpty();  
}
```

Example- Linear Probing

insert(76) insert(93) insert(40) insert(47) insert(10) insert(55)
 $76\%7 = 6$ $93\%7 = 2$ $40\%7 = 5$ $47\%7 = 5$ $10\%7 = 3$ $55\%7 = 6$

0		0		0		0		0	47	0	47
1		1		1		1		1		1	55
2		2	93	2	93	2	93	2	93	2	93
3		3		3		3		3	10	3	10
4		4		4		4		4		4	
5		5		5	40	5	40	5	40	5	40
6	76	76	76	47	76	6	76	6	76	6	76

probes: 1

1

1

3

1

3

2. Quadratic Probing

- In quadratic probing,
- When collision occurs, we probe for i^2 'th bucket in i^{th} iteration.
- We keep probing until an empty bucket is found.

Quadratic Probing

$$f(i) = i^2$$

- Probe sequence is

- $h(k) \bmod \text{size}$
- $(h(k) + 1) \bmod \text{size}$
- $(h(k) + 4) \bmod \text{size}$
- $(h(k) + 9) \bmod \text{size}$
- ...

- findEntry using quadratic probing:

```
bool findEntry(const Key & k, Entry *& entry) {  
    int probePoint = hash1(k), numProbes = 0;  
    do {  
        entry = &table[probePoint];  
        numProbes++;  
        probePoint = (probePoint + 2*numProbes - 1) % size;  
    } while (!entry->isEmpty() && entry->key != key);  
    return !entry->isEmpty();  
}
```

Example – Quadratic Probing

insert(76)
 $76\%7 = 6$

0	
1	
2	
3	
4	
5	
6	76

probes: 1

insert(40)
 $40\%7 = 5$

0	
1	
2	
3	
4	
5	40
6	76

1

insert(48)
 $48\%7 = 6$

0	48
1	
2	
3	
4	
5	40
6	76

2

insert(5)
 $5\%7 = 5$

0	47
1	
2	5
3	
4	
5	40
6	76

3

insert(55)
 $55\%7 = 6$

0	47
1	
2	5
3	55
4	
5	40
6	76
